100nF C1

Unconnected LVDS input gives HI out on TTL side. Active XLinks input should be LO during reset. XMOS pins has internal pulldown. Transciever needs to be in HiZ during XMOS reset.

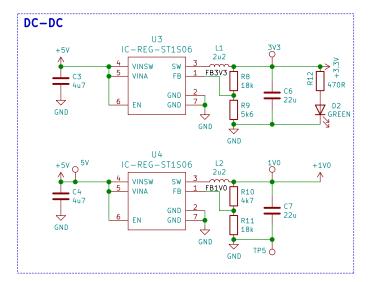

This should give hardware support for hotswap with unconnected active XLinks, with bootloader in Flash.

Cards can be power by USB or by the barrel jack 8-48V. Alternative "+48V" can come from a connected daugther card. Both USB and +48V should not be connected on the same PCB. USB ground should be isolated from power ground for PC safety.

Power ports are Global in the schematics.

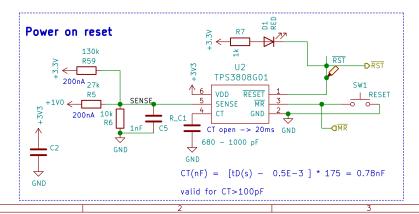

VDDIO/OTP_VCC and VDD can ramp up independently.

In order to reduce stresses on the device, it is preferable to make them ramp up in a short time frame of each other, no more than 50 ms apart.

RST_N and TRST_N should be kept low until all power supplies are stable and within tolerances of their final voltage.

If your design is powered by VBUS, then RST_N should go high within 10 ms of attaching to VBUS in order to ensure that USB timings are met. RST_N should be at least 1 ms after VDDIO good to enable the built-in flash to settle
